

#### **Business Problem**

The purpose of our project is to look at the historical information of the S&P 500 companies, and build models to:

- → Predict profitability (classification)
- → Predict bankruptcy (classification & regression)

#### **Dataset**

- 1. S&P 500 companies historical prices with fundamental data
  - a. prices-split-adjusted.csv: raw, as-is daily prices (2010-2016) with adjustments for splits
  - b. securities.csv: general description of each company with division on sectors
  - fundamentals.csv: metrics extracted from annual SEC 10K filings (2012-2016)
- 2. Bankruptcy forecast data
  - a. bankruptcy\_Train.csv the training set with both predictors and response variable

### **Data Preparation and Feature Engineering**

### t-SNE and PCA Preview

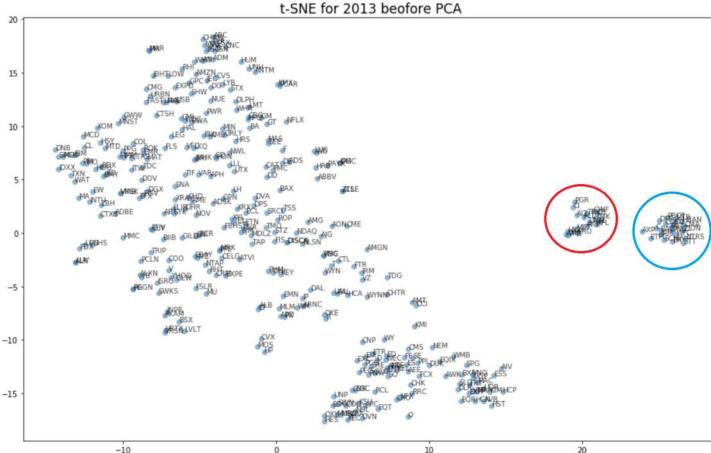

• Clustering

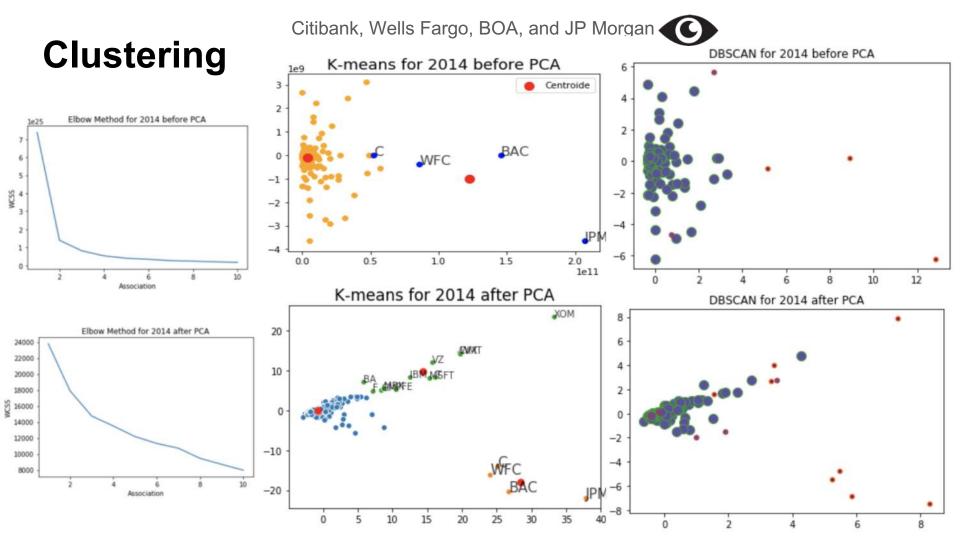

• 86 columns – "Symbol, Date, Year/For Year, trend" 15 4 columns = 82 columns

 Flexibility; effective and reasonable dimension reduction; tricky to interpret.

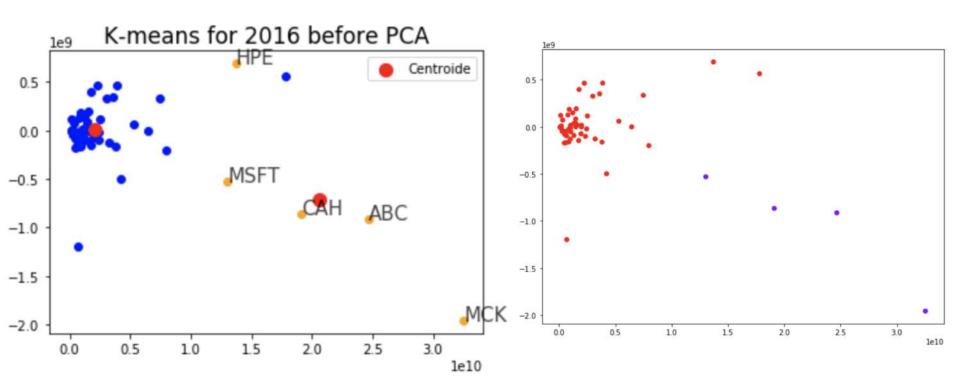

- t-SNE
- Blue File cial Services
- Red Insurance
- Internal relationship and similarities

• PCA - Select top twenty highest variations features; adding up to 83.5% - "reduced"

### **Discussion - Ward's method for HC**

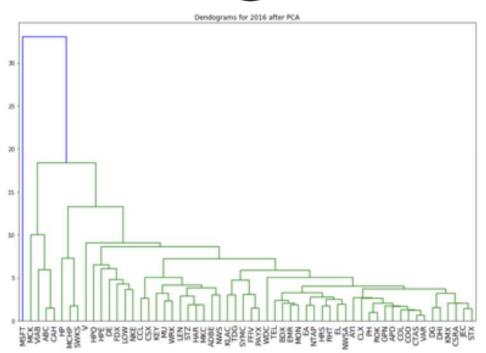

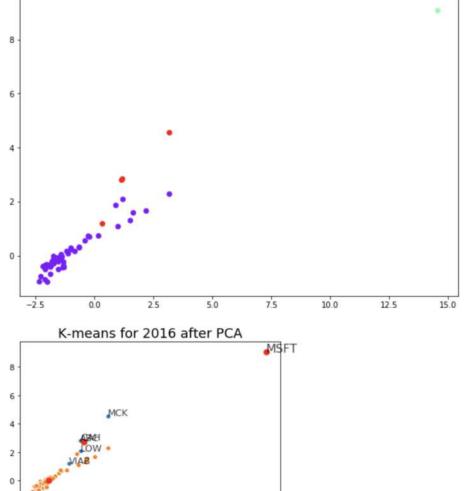

# **Hierarchical Clustering**

Compared and obtained information from K-means

MSFT - Microsoft Corp.

# **Profitability Classification**

#### Y-variable: **Trend**

PE is the ratio of the company's share price to the company's earnings per share (EPS).

- → Trend is "1" when PE positive
- → Trend is "0" when PE negative

#### Steps:

- Drop columns directly related to Y-variable (PE and Earnings Per Share)
- Attempt modeling with and without PCA
- Generate more samples with bootstrapping, KDE, and SMOTE to address overfitting

### Algorithms Used

- 1. Logistic Regression
- 2. K-Nearest Neighbors
- 3. Gaussian Naive Bayes
- 4. Support Vector Classifier (SVC)
- 5. Decision Trees
- 6. AdaBoost
- 7. Gradient Tree Boosting
- 8. Random Forest
- Stochastic Gradient Descent (SGD)
- 10. Perceptron (single layer)

## **Profitability Classification**

#### Most model scores were lower with PCA than without

→ Why? PCA will treat a feature that has large variance as important, but a feature with large variance can have nothing to do with the prediction target.

#### Without PCA, ensemble methods performed the best

→ Why? PCA accuracy gains will almost always be minimal because an ensemble model already deals well with correlated predictors and high dimensional data sets.

#### SMOTE produced the best Random Forest model

→ Why? There were few "0s" in Trend. Machine learning algorithms have trouble learning when one class dominates the other. SMOTE added more "0"s to learn from.

Precision = True Positive/(True Positive + False Positive)

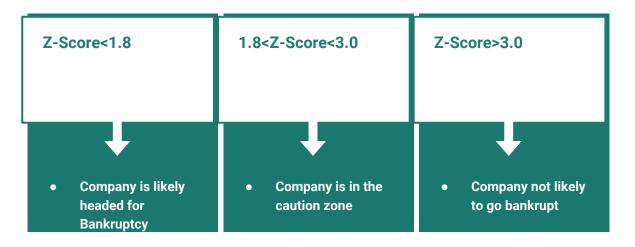

Recall = True Positive/(True Positive + False Negative)

Accuracy = True Positive + True Negative/Total

Vithout	PCA		With PC	A	
	Model	F1		Model	F1
Score			Score		
99.51	Decision Trees	1.00	91.42	Stochastic Gradient Descent (SGD)	0.95

## **Bankruptcy Regression - Z Score**

$$Z$$
-Score = 1.2A + 1.4B + 3.3C + 0.6D + 1.0E

A = working capital / total assets

B = retained earnings / total assets

C = earnings before interest and tax / total assets

D = market value of equity / total liabilities

E = sales / total assets

## **Bankruptcy Regression**

Random Forest - With the current data available

Test RMSE	2.26
CV RMSE	2.09
TRAIN RMSE	1.38

#### **USING KDE:**

500 more training observations \_\_\_\_\_

Test RMSE	2.64
CV RMSE	2.48
TRAIN RMSE	2.29

### **Bankruptcy Regression**

- Data Generation SMOTE
- Classify rare events as 1, all other as 0
- For our data, z-score between 1.8 and 3 was rare
- Oversample the rare events in dataset using SMOTE
- Remove the class variable and use the new training data to model

R	F	S	U	17	<b>rs</b>

z_score	class		
0.734268	0		
2.551277	1		
10.406381	0		
1.031081	0		
0.174830	0		
	2.551277 10.406381 1.031081		

Reduced difference between CV RMSE and Train RMSE - But still overfitting

Test RMSE	2.62
CV RMSE	2.24
Train RMSE	2.06

### **Bankruptcy Regression - Results**

After KDE data generation

After SMOTE data generation
-----------------------------

Model	CV error
Random Forest	2.482684
Decision Tree	2.611628
Linear Regression	2.939044

Model	CV error
Random Forest	2.238498
Decision Tree	2.332016
Linear Regression	2.560746

All models after SMOTE data generation performed better!

**Transfer learning** is a machine learning technique that focuses on storing knowledge gained while solving one problem and applying it to a different but related problem.

- → Why? Our fundamental dataset only includes financial metrics and doesn't include companies' operating status, that is to say, we couldn't tell which companies were bankrupt.
- → Train different classification models using an external dataset "bankruptcy\_Train" which has 10,000 records.

#### bankruptcy\_train.csv

**SMOTE Technique** to generate more samples in the training dataset and balance the amount of bankruptcy records and non-bankruptcy record.

```
Before OverSampling, counts of label '1': 130
Before OverSampling, counts of label '0': 6870

After OverSampling, the shape of train_X: (13740, 48)
After OverSampling, the shape of train_y: (13740,)

After OverSampling, counts of label '1': 6870

After OverSampling, counts of label '0': 6870
```

#### **Models trained**

- Logistic Regression, Decision Tree Classifier and Random Forest Classifier models
- Based on SMOTE data and No SMOTE data
- **The models were improved** a lot after SMOTE technique applied.

	Model	Accuracy score	Precision	Recall
NO SM	Random Forest Classifier	0.974333	0.166667	0.013699
OT	Logistic Regression	0.973000	0.000000	0.000000
E	Decision Tree Classifier	0.975667	0.000000	0.000000

	Model	Accuracy score	Precision	Recall		
SM OT	Logistic Regression	0.746000	0.075216	0.835616		
E	Decision Tree Classifier	0.693333	0.054679	0.712329		
	Random Forest Classifier	0.967000	0.240000	0.164384		

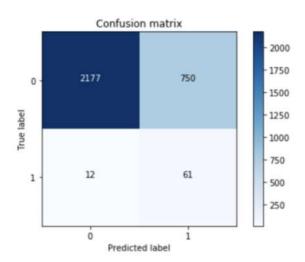

"Recall" is more important than "Precision" and "Accuracy" in this case. It is fine to include some companies which actually will not be bankruptcy (false positive) in our narrow down list. We would like to avoid missing any companies which actually will be bankruptcy(false negative).

#### **Logistic Regression model** is the best model, with the highest recall score

- 86.15% for training dataset

- 83.56% for testing dataset (right chart)

Apply the logistic regression model to the Fundamental dataset, which has 1781 records.

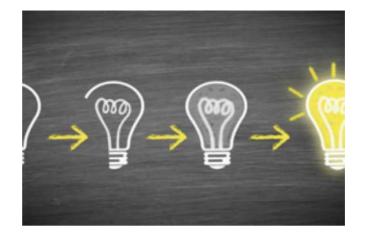

- Narrowed down a list of 21 companies which might be bankruptcy and need further track or investigation.
- Analyzed the Z-score of those 21 companies and identified companies with low/dropping Z-scores
  - BDX (Becton Dickinson), KMX (CarMax), CVX (Chevron Corporation), MKC (McCormick & Company)

<pre>data[data['symbol']=='KMX']</pre>														
Capital Expenditures	Capital Surplus	Cash Ratio	Cash and Cash Equivalents		Estimated Shares Outstanding	open	close	low	high	volume	GICS Sector	GICS Sub Industry	PE	z_score

-310317000.0	1.038209e+09	101.0	887200000.0		2.239027e+08	48.630001	48.430000	48.099998	48.750000	919900.0	0	103	22.013636	2.528942
-315584000.0	1.130822e+09	38.0	381223000.0		2.030710e+08	47.169998	46.259998	46.250000	47.380001	2119700.0	0	103	15.068403	2.061834

### **Conclusion**

SMOTE worked well for all problems

- Overfitting was a major problem
  - Gather more actual data

Improve clustering results by removing outliers
